

Interconnected — IT Lane: Full Handoff (System Migration)

Prepared by: Mack (IT lane) · **Date:** Wednesday, September 24, 2026 **For:** the agent taking over IT. Assume you have nothing else — no chat history, no prior briefs. This file is self-contained and supersedes `Mack_Domain_Scout_Interconnect_2026-08-24.md` (whose findings are folded in below, since session outputs don't survive migrations). **Verified against:** live DNS and the live site on Sep 24, 2026. Every claim below is tagged **[verified Sep 24]** (checked today, from this session), **[cross-ref]** (verified today by another lane's Sep 24 handoff), or **[unconfirmed]** (instructed but never confirmed executed — treat as not done).

0. What this lane is

You are **Mack, IT Manager** at **Interconnected** (rename to "Interconnect" proposed, **not cleared** — see §4). You own website hosting and deployment, domains and DNS, Google Workspace email infrastructure, account security, connected services, and infrastructure decisions. You report to **Buford** (Co-CEO, home base) and **Noah** (Founder & CEO, final say, non-technical but fast; give the *why* in one sentence then exact numbered click-paths; he's often on his phone; screenshots resolve most issues; he prefers honest pushback over validation).

Lanes cannot talk to each other; Noah carries files. **Write every output for cold handoff.** Peers: Dex (product — owns everything *inside* `index.html` ; you own everything around serving it), Sonny (BD — the outreach campaign your email infrastructure carries), June (marketing), Pearl (fundraising/co-founder), Ada (legal), Gus (CFO).

Standing rules of this lane:

1. **Deploy only when Noah hands you a file and says deploy.** Never proactively. Flag issues; don't act unasked.
2. **Never edit the contents of** `index.html` . Move it, verify it, revert it from git history if a deploy breaks — the insides are Dex's.
3. **Never touch MX, SPF, or DKIM records.** Absolute. (Full never-touch list in §7.)
4. Everything without a connector (Squarespace, Google admin, GitHub until a connector exists — see §5) is advise-and-verify: exact click-paths, Noah executes, every change logged in your outputs so home base holds the record.
5. Findings before purchases. Deliverability is sales infrastructure. Security posture checked without being asked twice.

Onboarding gap you inherit: the original `IT_Infrastructure_Briefing.md` — described as the complete technical inheritance (every configuration, credential location, past incident) — **was never**

delivered to this lane. Only the shorter `Mack_IT_Brief.md` arrived (Aug 24). Everything below was built from that brief plus direct verification. If the infrastructure briefing surfaces, it may contain incident history and credential locations this file lacks — reconcile, and flag conflicts to Noah.

1. Infrastructure state of record

Serving stack [verified Sep 24]

- **Live site:** <https://www.joininterconnected.com> — GitHub Pages from repo `noahaustin15/interconnected-demo`, current commit `8335d29` (Aug 26; no commits since) [cross-ref: Dex handoff, repo checked Sep 24].
- **HTTPS works end-to-end:** `http://joininterconnected.com` redirects to `https://www.joininterconnected.com` with a valid certificate [verified Sep 24 by live fetch]. The *Enforce HTTPS* checkbox state in Pages settings was never screenshotted back to this lane [unconfirmed], but the observable behavior is what the checkbox exists to produce — treat the task as functionally done, confirm the checkbox opportunistically next time someone is in Pages settings.
- **DNS (registrar: Squarespace Domains), full read as of today** [verified Sep 24]:

Record	Value	Status
A (apex) x4	185.199.108.153 / .109.153 / .110.153 / .111.153	Correct GitHub Pages set
www CNAME	noahaustin15.github.io	Correct — and proof the account transfer in §3 never happened
MX	1 smtp.google.com	Google's modern single-record form. Correct. Do not "fix" it to the legacy five-record set.
TXT (apex)	v=spf1 include:_spf.google.com ~all	SPF correct, untouched
google._domainkey TXT	RSA key present	DKIM is published and signing — good
_dmarc TXT	NXDOMAIN — record does not exist	DMARC was never created. Top open item, §6.

- **Site head tags serving live** [verified Sep 24]: `og:title`, `og:description`, `og:image` → `https://www.joininterconnected.com/og-image.png` (1200×630, absolute on the www host), `og:url`, `og:site_name`, `twitter:card summary_large_image` + **twitter set**, `theme-color`

#F7FAFF, color-scheme: light only. All under the **Interconnected** name. Asset files (og-image.png, favicon.svg, favicon.ico, apple-touch-icon.png, CNAME) confirmed at repo root [cross-ref: Dex, Sep 24].

Email [verified Sep 24 unless noted]

- Company email `noah@joininterconnected.com` on Google Workspace; inbox live and reconciled Sep 24 [cross-ref: Sonny handoff].
- Authentication: SPF  DKIM  **DMARC** . With Gmail/Outlook's bulk-sender rules, missing DMARC is the one gap that costs deliverability — and the BD lane's restart plan (Rick Randall reschedule, Chris Smith bump, Eric Bryant first touch) means sends are imminent.
- 27 outreach emails went out Aug 24–26; campaign dormant since, restarting now [cross-ref: Sonny].

Adjacent domains [verified Sep 24]

- `interconnecteddemo.com` — **no DNS records exist** (checked Aug 24 and again today). A Namecheap-purchased domain would be parked with DNS. Working conclusion: **never purchased**. Noah's 30-second confirmation (Namecheap → Domain List) was requested and never returned [unconfirmed]. Recommend the successor close this as "not owned" on Noah's one-line say-so.
- `interconnect.church` and `interconnectapp.com` — the scout's recommended primary and fallback — **still show no DNS today**, i.e. very likely still available and **definitely not purchased by us**. If the rename ever gets a green light, these get bought the same day — announcement before purchase is a squatting invitation.

2. Task scoreboard — verified vs. pending

The §4 task list from the Aug 24 brief, with the honest status. This lane had **one working session (Aug 24)**; no completion confirmations or screenshots were ever returned, and today's verification is what separates done from not.

#	Task	Status	Evidence
1	Domain scout for Interconnect	Done Aug 24 — findings + migration map delivered (folded into §4 below). Decision pending at home base ; rename not cleared [cross-ref: Sonny §1]	Scout report delivered Aug 24
2	Enforce HTTPS on Pages	Functionally verified — http→https redirect + valid cert live	[verified Sep 24]
3	DMARC record	NOT DONE . Click-path and exact values delivered Aug 24; <code>_dmarc</code> is NXDOMAIN today	[verified Sep 24] — #1 open item

4	2FA on Google + GitHub, recovery codes offline	Unconfirmed. Paths delivered Aug 24; no screenshot ever returned; not externally checkable	[unconfirmed] — #2 open item
5	Auto-renew on domain + Workspace billing	Unconfirmed. Same. Domain expiry date was requested for the record and never supplied	[unconfirmed]
6	interconnecteddemo.com status	Effectively resolved: no DNS then or now → presumed never purchased; needs Noah's one-line Namecheap confirmation to close	[verified Sep 24] + [unconfirmed]
7	hello@ alias	Not done (no Workspace session ever confirmed)	[unconfirmed]
8	Favicon + OG tags	Shipped and serving (commit <code>8335d29</code> , Aug 26 — the rename pause was overtaken by events; assets carry the <i>Interconnected</i> name, correctly, since the rename isn't cleared). Client-preview verification checklist never run — see §2a	[verified Sep 24] / [unconfirmed]
9	Uptime monitor (UptimeRobot-class)	Not done	—

2a. OG-preview verification — results and the outstanding checklist

What is verified (Sep 24, from the served page): the full OG/Twitter tag set is live, syntactically correct, image URL absolute on the canonical `www` host, dimensions declared 1200×630, `summary_large_image` card set. Everything a crawler needs is in place.

What was never verified: actual rendering in clients. This checklist was assigned Aug 24 and its completion never confirmed [cross-ref: Dex §6.3 says the same]. It takes five minutes with Noah's phone; run it once and log results:

1. **iMessage** — paste the URL in a **fresh** thread (any thread where the link was ever sent before will show the stale/bare preview forever). If even a fresh thread shows the bare link, it's Apple's cache — wait an hour and retry before changing anything.
2. **WhatsApp** — fresh thread; note the square crop behavior (the design keeps everything inside the center 630×630, so it should survive).
3. **Slack** — any channel/DM.
4. **Facebook Sharing Debugger** and **LinkedIn Post Inspector** — paste the URL; both force a fresh crawl and show exactly what they'll render. Run once, screenshot.
5. Expected card: brand-blue image, wordmark + tagline, title "Interconnected: your church, connected every day of the week." If the rename lands, `og-image.png` gets regenerated by **Dex** (his lane), and this checklist runs again.

3. GitHub account transfer — requested, instructed, not executed

In the Aug 24 session Noah asked to move hosting to another GitHub account. Full click-path was delivered (built-in **Transfer ownership**, never re-upload — it preserves git history, Pages config, and the `CNAME` file). **It never happened:** the `www` `CNAME` still points at `noahaustin15.github.io` [verified Sep 24] and the repo still lives under `noahaustin15` [cross-ref: Dex, Sep 24]. Noah also never answered the blocking question: **destination account name, and personal account vs. Organization.**

Standing recommendation, unchanged: a **free GitHub Organization** owned by Noah, repo transferred in — a co-founder later becomes a second owner without shared logins. A second personal account just relocates the single point of failure.

Condensed run for when it revives (full ordering matters): ① destination account exists, 2FA on, codes stored → ② old repo → Settings → Danger Zone → **Transfer ownership** (personal destinations must accept via email within 24h; own Org is instant) → ③ move the **domain verification**: remove `joininterconnected.com` from old account's Settings → Pages → Verified domains; add on the new account; put the new `_github-pages-challenge-<name>` TXT in Squarespace; Verify; delete the old challenge TXT only → ④ Squarespace: edit `www` `CNAME` data to `<newname>.github.io` — the four apex A records, MX, SPF, DKIM, DMARC all stay untouched → ⑤ new repo → Settings → Pages: custom domain should persist via the `CNAME` file; wait for DNS check, then cert, then Enforce HTTPS — never remove/re-add the domain while waiting → ⑥ verify `http://` apex redirects to `https://www.` with padlock, incognito, on cellular → ⑦ log everything; re-point any hardcoded `noahaustin15.github.io` references; a future GitHub connector must be authorized against the **new** account. Expect minutes of propagation wobble; do it on a day with no pastor meeting.

4. The rename ("Interconnect") — scout findings of record + migration map

Status: rename NOT cleared. All public assets, outreach, and email correctly still say **Interconnected** on the existing domain [cross-ref: Sonny §1]. Ada's trademark read status is unknown to this lane. The go/no-go at home base never happened. Nothing below executes without it.

Scout findings (Aug 24, availability re-spot-checked Sep 24):

- `interconnect.com` — taken; owner posts "not for sale, don't ask" since 2019. Dead at any price.
- `joininterconnect.com` — **taken by a live product:** "InterConnect," an AI career-guidance platform pitched on "meaningful connections." Kills the join-prefix consistency option *and* is a brand-collision flag.
- `getinterconnect.com` — taken (InterOptic, data-interconnect hardware). `interconnect.app`, `.co`, `.org`, `.net`, `.us`, `.me`, `interconnecthq.com` — all taken.
- `interconnect.io` — GoDaddy brokered "get a price" listing = negotiated four-to-five figures. Not

for our stage.

- **Open (no DNS then or now; only a registrar cart proves it):** `interconnect.church`, `interconnectapp.com`, `useinterconnect.com`, `tryinterconnect.com`, `myinterconnect.com`, `interconnectchurch.com`.
- **Recommendation on record:** primary `interconnect.church` (the address is the positioning — `noah@interconnect.church` says the category before a pastor reads a word; TLD familiar to this buyer; deliverability rides on SPF/DKIM/DMARC, not TLD), fallback `interconnectapp.com` (nearest open .com). If green-lit, **buy both** (~\$50/yr total) the same day, before any announcement.
- **Flag for Ada / the go-no-go (delivered Aug 24):** "Interconnect" is crowded in software; two collisions sit near our category — the `joininterconnect.com` platform and an App Store app "Interconnect Network" (private, verified-member community feed with connect requests and moderated posts). A pastor Googling "Interconnect app" will not find us first.

Migration map (cost of saying yes — sequencing principle: site and email move on different days; email moves last; active pastor threads never see a sender change mid-thread):

1. Green light → buy primary + fallback, auto-renew on.
2. Workspace: add new domain as a **domain alias** (Admin → Account → Domains → Manage domains → Add a domain → *Alias domain*) — **not** a secondary domain (creates separate users — wrong tool), and no tenant migration (never needed). Alias = `noah@` at both domains lands in the *same inbox*, so every reply to an old thread still works. Google's TXT verification + the new domain's MX/SPF/DKIM/DMARC go in the **new** domain's DNS only. DMARC on the new domain must exist **before** the first send from it. (Later, optional: *Change primary domain* is one Admin click, but check first whether the Workspace subscription was bought via Squarespace/Google Domains, which can block it; not needed for launch.)
3. Dex ships the renamed build; **domain switch and copy change land the same day** (favicon/OG regeneration is his, in the same commit).
4. New domain DNS: same four apex A records; `www` CNAME → the GitHub Pages host of whatever account owns the repo by then.
5. Pages custom-domain switch on the repo (writes a `CNAME` file — a commit, but not to `index.html`); wait for DNS check → cert → Enforce HTTPS; no toggling.
6. `joininterconnected.com` **is kept forever** — a Pages repo serves one custom domain, so prepare *before* step 5 a tiny redirect repo (one-line meta-refresh/JS `index.html` , custom domain `www.joininterconnected.com` , HTTPS enforced). This preserves every `https://` link in every pastor email. Squarespace's own forwarding is the lesser option (HTTPS on forwarded links unverified). True 301s only matter for SEO, which at 27 emails is not a factor. Old domain's MX/SPF/DKIM/DMARC untouched throughout — email never blinks.
7. Email cutover, two-phase: new first-touch outreach from the new address (Gmail → Settings → Accounts → *Send mail as* → alias → default) once its DNS auth is live; existing threads keep the old sender until they close; old address stays alive as an alias indefinitely.

8. Housekeeping: signatures, Workspace org name, optional repo rename, `hello@` on both, Gmail connector unaffected (bound to the account, not the domain). Total: ~2 hours of Noah across two sittings, ~\$50/yr, a day of DNS/cert waiting. Only the announcement is irreversible.

5. Access inventory

System	Account / identity	Who holds access	Connector state	Notes
GitHub	<code>noahaustin15</code> (personal) · repo <code>interconnected-demo</code>	Noah only	No connector was ever enabled in this lane. The Aug 24 brief said the lane was connected; the chat's tool list never contained GitHub, flagged to Noah Aug 24, never resolved. All deploys remained Noah-manual all period.	If the new system grants a GitHub connector: verify access against the repo before the first deploy, and against the <i>new</i> owner if §3's transfer ever executes. 2FA/recovery-code status [unconfirmed].
Squarespace Domains	<code>joininterconnected.com</code> (registrar + DNS + the never-touch records)	Noah only	None (by design)	Auto-renew state and expiry date [unconfirmed] — get both logged. A lapse kills site + email simultaneously.
			Gmail connector live on two other lanes: Sonny (BD — reads	Any Workspace "third-

Google Workspace	noah@joininterconnected.com (admin = Noah)	Noah	and drafts, never sends ; Noah sends everything personally) and Buford (oversight). This IT chat also had Gmail + Google Drive connectors available and never used them .	party app access" security alert is most likely these connectors — legitimate, but confirm before dismissing. Least-privilege note for the new system: the IT lane doesn't need inbox access to do its job; decide deliberately whether it keeps Gmail/Drive. 2FA enforcement + backup codes [unconfirmed].
Namecheap	Historical account (existence per brief)	Noah	None	Contents unverified; <code>interconnecteddemo.com</code> presumed never purchased (\$1).
Recommended-but-unbought domains	<code>interconnect.church</code> , <code>interconnectapp.com</code>	Nobody (open as of Sep 24)	—	Purchase only on rename green light — then immediately.
Anthropic / claude.ai project "InterConnected"	Project files	Noah + all lanes	—	The durable record. Session workspaces get recycled (the BD lane lost its xlsx tracker this way) — anything that must survive goes into the project as a file.

Single-founder reality, restated: the GitHub account and the Google account *are* the company. 2FA + offline recovery codes on those two is the highest-leverage security action available, and it is still [unconfirmed].

6. Open items for the successor, in priority order

1. **DMARC — create it.** Verified absent today; outreach restart is imminent. Squarespace: `account.squarespace.com` → Domains → `joininterconnected.com` → DNS → DNS Settings → Custom records → Add record → Host `_dmarc` · Type `TXT` · Data `v=DMARC1; p=none;`

`rua=mailto:noah@joininterconnected.com; fo=1` → Save. Touch nothing else on that page.

`p=none` changes no delivery — it starts reports; read the first XML for Noah, tighten to

`p=quarantine` after a clean month. Verify at mxtoolbox.com/dmarc.aspx after ~1 hour. **Do this before, not after, the Rick Randall / Chris Smith / Eric Bryant sends if at all possible — and don't let Noah do the DNS edit from his phone; the TXT field truncates on small screens.**

2. **Confirm 2FA + recovery codes** on Google and GitHub (paths: GitHub → Settings → Password and authentication; Google → myaccount.google.com → Security → 2-Step Verification; enforce tenant-wide at admin.google.com → Security → Authentication). Screenshots of end states go in the log.
3. **Auto-renew + expiry dates** (Squarespace domain overview; admin.google.com → Billing → Subscriptions) — log the dates; check the card isn't expiring.
4. **Recover** `IT_Infrastructure_Briefing.md` — the technical inheritance this lane never received. It wins over this file on configuration details it documents; flag conflicts.
5. **Close interconnecteddemo.com** on Noah's one-line Namecheap check.
6. **GitHub transfer decision** (§3): Org vs. stay-personal — get it decided and logged either way; execute per §3 if go.
7. **Rename go/no-go** (§4): surface it at home base; it has been pending since Aug 24 and the recommended domains sit unprotected while it waits.
8. **Run the OG client-preview checklist** (§2a) — five minutes, then log.
9. `hello@` **alias** (Admin → Directory → Users → Noah → Add alternate email) — free, do it alongside any Workspace session.
10. **Form service for pilot requests** (Formspree-class; Dex's standing request — this lane creates the account, Dex wires one small edit). Removes the only conversion path's dependency on the visitor's mail app. Recommended.
11. **Uptime monitor** (UptimeRobot-class free tier on the live URL).
12. **Analytics account** (Plausible/Fathom-class) — *paused by Noah*; act only when he unpauses; Dex holds the implementation spec.

7. Decisions on record (don't relitigate without new information)

- **GitHub Pages stays** for the marketing site; revisit only on a concrete trigger (server-side form capture, recurring deploy pain).
- **The site stays dependency-free** (Google Fonts only) and **light-mode locked** — scar tissue from real incidents.
- `joininterconnected.com` **never lapses**, rename or not — every link ever sent must keep working.
- **Never-touch list:** MX (`1 smtp.google.com` — modern single-record form, not broken), SPF TXT,

DKIM (`google._domainkey`). DMARC, once created, joins the change-controlled set.

- **Never toggle** the Pages custom domain / Enforce HTTPS while a cert is provisioning.
- **Deploys only on Noah's explicit hand-off; `index.html` contents are Dex's**; deploy filename is `index.html` exactly (Windows hides extensions — the `.html.html` trap).
- **The future product stack** (React Native / Node / PostgreSQL / AWS-or-GCP) belongs to the eventual technical co-founder; this lane's role then is accounts, access, domains.
- **We never handle payments**; the Give button stays a deep-link placeholder.

8. What "good" looks like in this lane

Exact click-paths with the why in one sentence; verification over recollection (today's DNS read is the model — check, don't assume); findings before purchases; every DNS or account change logged to home base; the never-touch list respected absolutely; deliverability treated as the sales infrastructure it is; security posture checked without being asked twice; and honest pushback when a request risks the domain, the email, or the deploy pipeline — Noah expects it and respects it.
